## **Asset-Based Lending smart contract**

Author: Dmitry Petukhov (https://github.com/dgpv)

Date: 2020-05-04

## **Contract premise**

Alice possesses certain quantity of asset *Principal\_Asset* that she does not currently utilize, but wants to extract some value from.

Bob possesses asset  $Collateral\_Asset$ , but needs some P amount of asset  $Principal\_Asset$  temporarily.

Bob does not want to sell *Collateral\_Asset*, because he predicts that its value or utility will be higher in the future than what the current market value, for tax reasons, etc.

Bob is willing to pay the for the temporary use of P while offering C amount of  $Collateral\_Asset$  as a guarantee of repayment to the creditor.

Contract can be terminated at any time by any settlement that is mutually agreed by the two parties.

## **Basic Asset-Based Loan contract**

 $t_0$  is the point in time when contract begins

 $t_1$  is the point in time when the pre-agreed duration has passed since  $t_0$ 

Interest rate R is pre-agreed

Alice is willing to give out *P* to Bob, provided that:

- Before  $t_1$ , she will receive P + P \* R
- Otherwise, at or after  $t_1$ , she will be able to claim C

Bob is willing to freeze C for certain period, provided that:

- He will receive *P* immediately
- If P+I is repaid before  $t_1$ , he can recieive C back

Bob agrees that if P + I is not repaid before  $t_1$ , Alice can claim C for herself.

To enter the contract, Alice and Bob create and cooperatively sign a transaction that:

- Sends *P*, provided by Alice, to Bob's address
- Sends C, provided by Bob, to the address of a script that enforces the terms of the contract above

This contract is simple, but limited. It requires for principal to be repaid in one lump sum, it is often preferable for the principal to be repaid in portions over time.

## **Asset-Based Loan contract with partial repayments**

The repayment is split into N installments.

Up to M consecutive missed payments is tolerated.

There are N + M + 1 fixed time periods over which the contract can progress.

The duration for a single period is pre-agreed, all periods have the same duration.

The rates used for calculation of interest or surcharge are pre-agreed:

- $R_D$  is the rate for regular repayments *due*
- $R_E$  is the rate for surcharge on *early* repayments
- $R_{L(1)} \dots R_{L(M)}$  are the rates for surcharge on *late* repayment:  $R_{L(1)}$  is applied when one payment is missed,  $R_{L(2)}$  is applied when two consecutive payments are missed, and so on

 $t_i$  is the point in time at the beginning of each period,  $i \in [0, N+M]$ 

n is the number of partial repayments,  $n \in [0,N]$ 

m is the number of missed payments,  $m \in [0, M+1]$ 

B is the outstanding principal balance

$$F_P=rac{P}{N}$$
 is installment size (the "Fraction of  $P$ ")

 $D=\min\{F_P*(m+1),B\}$  is the portion of the balance currently due to be repaid [1]

 $L = \min\{F_P * m, B\}$  is the amount the repayment is *late* on

At  $t_0$ :

- n = 0
- m = 0
- $\bullet$  B=P

Alice is willing to give out P to Bob, provided that:

- ullet Before each  $t_i, i>0$  she will receive  $D+D*R_D+L*R_{L(m)}$  , and then:
  - *n* will be incremented
  - *m* will be reset to 0
  - *B* will be decreased by *D*
- Otherwise
  - *m* will be incremented
  - $\circ$  if m > M, she will be able to claim C

Alice agrees that before  $t_{N-1}$ , B can be set to 0 if Bob repays

$$B + D * R_D + (B - D) * R_E + L * R_{L(m)}$$

Bob is willing to freeze C for certain period, provided that:

ullet He will receive P immediately

ullet When the condition B=0 is reached during contract execution, he can receive C back Bob agrees that Alice can claim C for herself if the condition m>M is reached during contract execution

To enter the contract, Alice and Bob create and cooperatively sign a transaction that:

- Sends *P*, provided by Alice, to Bob's address
- ullet Sends C, provided by Bob, to the address of a script that enforces the terms of the contract above
- [1] With presented simple formula, D for the last repayment equals  $P \pmod{N}$ . In most cases P will likely be much larger than N, and last repayment will be very small in this case. Simpler formula is easier for understanding, but for real application, it makes sense to just make the last repayment slightly bigger than others, and the more complex formula should be used:

$$D = \left\{egin{aligned} F_P*(m+1) & ext{if } (F_P*(m+1)+P \pmod N)) \geq B \ B & ext{otherwise} \end{aligned}
ight.$$
